

POSTERIOR DERIVED QUANTITIES

 This sample can be used to calculate any quantity of interest:

 $\{\theta_1, \dots, \theta_N\} \sim P(\theta \mid y)$

For example, the posterior mean is just:

$$\frac{\theta_1 + \theta_2 + \dots + \theta_N}{N} \approx \sum_{N} \theta P(\theta \mid y)$$

 $\theta \in \Omega$

Other quantities

- Any other functions of the parameters can be estimated from the samples.
- A common use is to calculate contrast between categorical levels, estimating the difference between groups.
- Quantiles, values above a value, confidence intervals...

POSTERIOR DERIVED QUANTITIES

 This sample can be used to calculate any quantity of interest:

$$\{\theta_1, \dots, \theta_N\} \sim P(\theta \mid y)$$

For example, the posterior mean is just:

$$\frac{\theta_1 + \theta_2 + \dots + \theta_N}{N} \approx \sum_{\theta \in \Omega} \theta P(\theta \mid y)$$

BUILDING A MODEL

My first bayesian regression model

Given the matched pairs:

$$(x, y) = \{(x_1, y_1), \dots, (x_n, y_n)\}$$

• Define a likelihood:

$$y_i \sim Normal(\mu_i, \sigma)$$

$$\mu_i = \alpha + \beta x_i$$

$$P(y \mid \theta)$$
